INLAND NAVIGATION ECONOMICS WEBINAR SERIES

#7 – Navigation Component Engineering Reliability

US Army Corps of Engineers BUILDING STRONG®

Required Information for Consequence Analysis

- Annual Hazard Rate for time dependant components
- Single PUP for non-time dependant components
- Consequence Event Tree
 - Significant consequences
 - Various levels of repair
 - Costs to repair and other damages
- Updated hazard rates for repaired components
- Cost associated with fix as fails vs. scheduled repair prior to failure.

Overview

- Reliability Analysis
- Engineering Assessment
- Calculating Hazard Function
- Event Trees and Consequence Levels

Reliability Analysis

Reliability:

Probability that a system will perform its intended function for a specific period of time under a given set of conditions.

 $R = 1-P_f$

Reliability is the probability that unsatisfactory performance will not occur.

Risk: Pf x Consequences = Risk

Methods of Reliability Analysis

Hazard Function Analysis

- Time Dependant Reliability Models
- Non-time Dependant Reliability Models
- Expert Opinion Elicitation
- Historical Frequency Method

Engineering Assessment

- Systematic assessment of all components or infrastructure
- What components should be evaluated? What are the critical components?
- Numerical Screening Method
 - Ranking based on different categories
 - Categories weighted based on criticality
 - ► Relative ranking
 - Consistency is important

Example Screening Criteria

ASSESSMENT CATEGORIES

- Planned replacement/upgrade? Funding in place? Yes/No
- Component Redundancy 0.1
- Current Condition of component 0.1
- Likelihood of future problems 0.3
- Relative costs to replace/upgrade and quantity 0.15
- Impact to navigation/outage time 0.25
- Other impacts 0.1

Example Screening Criteria

- Each category was rated 1-5 by the assessment team.
- I being the worst and 5 being the best
- All ratings were multiplied by the category multiplier and summed
- Components with the smallest ratings moved to the top of the list.
- Assessment team reviewed list and came up with a cut off point and reviewed excluded components to make sure all that were thought to be critical were included.
- Components evaluated individually.

 $\textbf{BUILDING STRONG}_{\texttt{R}}$

Calculating PUP

Hazard Function Analysis

- Time Dependant Reliability Models
- Non-time Dependant Reliability Models

Expert Opinion Elicitation Historical Frequency Method

Hazard Function Analysis

- Computes the rate of change at which the probability changes over a selected time step (usually annually).
 - ► Not a snapshot in time.
 - Uses Monte Carlo simulations to calculate probability of failure.
 - ► Time dependant or Non-time dependant

Hazard Function Analysis

Hazard function h(t) is the conditional probability of unsatisfactory performance of a structure or component at a time (t) given that it has survived up to the selected time.

$$h(t) = f(t)/R(t)$$

 $f(t) = pdf at time t + \Delta t$

R(t) = cmumulative reliability up to time t

When using Monte Carlo simulations h(t) can be simplified to:

h(t) = # failures $(t_i) / #$ of survivors (t_{i-1})

Time Dependant Reliability Models

- Probabilities of Unsatisfactory Performance that degrade over time
 - Hydraulic Steel Structures (crack propagation)
 - Monolith instability due to scour
 - Deteriorating concrete
 - Mechanical/electrical equipment

Failure of Miter Gate Member due to Fatigue Cracking

BUILDING STRONG_®

Miter Gate Fatigue Cracking

15

- Failure limit state was set to 10 inches.
- Finite element model used to calculate stresses.
- Failure due to stress reversals (tension/compression)
- Monte Carlo simulation varying stress concentrations, corrosion rates, gate component wear, material properties, and initial crack size.

BUILDING STRONG_®

Crack Growth for Stiffener Plate

Cracking of DS Girder Flanges

Effect of Traffic Increase on Stiffener Plate Cracking

Miter Gate Hazard Function

Monolith Instability due to Scour

BUILDING STRONG®

Monolith Instability due to Scour

Monolith Instability due to Scour

- Probabilistic Analysis using Excel and @Risk
- Variables
 - Erosion Rate
 - Shear strength at the concrete rock interface
 - Bearing capacity of rock
 - ► Ship pull force
 - ► Pool elevation

ING STRONG_®

West Center Pier Hazard Function

Calculating PUP

Hazard Function Analysis

- Time Dependant Reliability Models
- Non-time Dependant Reliability Models
- Expert Opinion Elicitation
 Historical Frequency Method

Non-time Dependant Reliability Models

Probabilities of Unsatisfactory Performance that do not vary with time:

- Stability Analysis w/o scour or another time dependent parameter
- Seismic Analysis

Non-time Dependant Reliability Models

- Probability of the loading occurring on a given year
 - Seismic event
 - Pool loading
- Probabilistic analysis varying foundation parameters and uplift conditions
- PUP is constant for the entire study period.

Calculating PUP

Hazard Function Analysis Time Dependant Reliability Models Non-time Dependant Reliability Models Expert Opinion Elicitation Historical Frequency Method

EOE

- Expert Opinion Elicitation is used when analysis cannot be performed or to supplement analysis findings.
- Formal process with a facilitator, panel of experts, observers and a recorder.
- Failure rates elicited for pre determined periods (1, 10 and 25 year)
- Produces an annualized reliability that changes through the study period

Example EOE Response Table

Event Name	Full Description of Issue	Expert-opinion elicitation							
			First Response		Second				
The miter gate machinery performs unsatisfactorily and fails to open/ WI close the miter un gates. the	hat are the probabilities of satisfactory performance for e miter gate machinery in

h(t) = f(t)/R(t)

h(t) = (0.59 - 0.55)/0.59 = 0.068

Calculating PUP

Hazard Function Analysis Time Dependant Reliability Models Non-time Dependant Reliability Models Expert Opinion Elicitation Historical Frequency Method

Historical Frequency Method

- Use of known historical information from project records to estimate failure rates of components.
- USACE projects do not have enough historical failure performance to develop future probabilities.
- This method is being implemented together with Expert Elicitation for levee failures.

Requirements for Consequence Analysis

34

Consequence Event Tree

- Interface between engineering and consequences.
- Provides the level of consequence and repair associated with unsatisfactory performance.
- Consistent with the reliability analysis limit state modeling
- Developed for individual maintenance strategies.

Consequence Levels and Event Trees

		Annual				Effect on Overall	
Component	Hazard Rate		Level of Repair	Closure Time	Repair Cost	Component Reliability	
		Annual					
		Reliability Value					
		(1 - Annual Hazard Rate)					
Horizontally-framed			New Gate 5%	365 days in year 1 —	\$13,150,000	Assume R = 1.0 for All Fut	ure Years
Miter Gate				90 days in year 2 —	\$3,150,000		
		Annual	Major Repair 35% ———	45 days in year 1 —	\$1,575,000	Move Back 5 Years	
		Hazard Rate		45 days in year 2 —	\$1,575,000		
			Temporary Repair 60% —	45 days in year 1 —	\$3,575,000	Assume R = 1.0 for All Fut	ure Years
			Replace 1st Set of Gates —	45 days in year 2 —	\$3,575,000		
			Replace 2nd Set of Gates	30 days in year 3 —	\$5,050,000		
SCHEDULED	REPLAC	EMENT BEFORE FAILUR	E INFORMATION				
Year 1 30 Days of C	Year 1 30 Days of Closure @ \$5,050,00 Year 2 30 Days of Closure @ \$5,050,000						
Future Reliabil	ity Will Eq	ual 1.0 Throughout Remain	der of Study Period
